# Guide To Wheat Hardness

USDA LIBRARY  
OCT 6 '89

ARLINGTON BRANCH

## Abstract

Slaughter, David C. 1989. Guide to Wheat Hardness. U.S. Department of Agriculture, Agricultural Research Service, ARS-79, 89 pp.

This publication presents the hardness scores for about 1,900 wheat samples representing more than 125 varieties and 10 States. The scores were measured objectively by a near-infrared procedure and show that wheat hardness varies with variety, growing environment, and growing location. The scores represent an important first step in the development of a new and objective wheat classification system.

KEYWORDS: near-infrared reflectance, wheat, wheat classification, wheat hardness.

Tables are reproduced essentially as supplied by the author.

Trade names are used in this publication solely to provide specific information. Mention of a trade name does not constitute a guarantee or warranty of the product by the U.S. Department of Agriculture or an endorsement by the Department over other products not mentioned.

## GUIDE TO WHEAT HARDNESS

David C. Slaughter

### Introduction

The Official U.S. Standards for Wheat divides wheat into seven classes, such as soft red winter, hard red winter, hard red spring, and white. Wheat class, the first determination made on wheat after dockage removal, is used as an indicator of appropriate end use. Currently, wheat class is determined solely by visual inspection of kernel color and such morphological characteristics as kernel shape and length, and shapes of the germ, crease, and brush. If a wheat sample has the specified external kernel characteristics of a hard or soft wheat, it is so identified without any physical determination of its relative hardness or softness.

However, many newly released varieties no longer exhibit the traditional visual characteristics of their class. For example, some soft red winter varieties have kernel characteristics previously exhibited only by hard red winter varieties and vice versa. Since the "hard" or "soft" designation provides important information on tempering and milling requirements and end-use performance, proper classification of wheat is important to orderly marketing and utilization.

The U.S. Congress in the Food Security Act of 1985, PL-99-198 (farm bill), charged the Federal Grain Inspection Service (FGIS) and the Agricultural

Research Service (ARS) to collaborate in the development of a new system of classifying wheat. In June 1986, the Administrator of FGIS established the Wheat Classification Working Group (WCWG) to guide and oversee the ongoing effort to develop such a system. WCWG membership was drawn from all relevant sectors of the wheat industry, including growers, seed producers, breeders, millers, end users, and trade organizations. The primary goal of the collaborative effort by FGIS, ARS, and WCWG is to establish an objective, accurate, and efficient system for classifying wheat. Also, the WCWG has insisted that the system pose no major risk of market disruption. Consistent with these requirements, the collaborators identified the development of an objective method for measuring hardness as their first objective.

Wheat hardness, despite wide usage, is a concept for which no physical-property definition has been universally accepted. In 1986, Norris et al. (in press) developed a definition of wheat hardness based on certain near-infrared reflectance (NIR) measurements of ground wheat samples. The basis of their definition is that (1) the particle size of ground wheat correlates directly with the hardness of the wheat kernel and (2) near-infrared light is more highly absorbed by larger particles than by smaller particles. They developed a standardized procedure for grinding wheat samples, taking the required NIR measurements, and translating the measurements into hardness scores. Their procedure was verified by a collaborative study and accepted as a standard by the American Association of Cereal Chemists (AACC) (1986). The WCWG has endorsed NIR hardness scores as the reference definition of wheat hardness; it has also endorsed the development of any new classification system that is based on those scores.

---

Agricultural engineer, Instrumentation Research Laboratory, USDA-ARS, Beltsville Agricultural Research Center, Beltsville, MD 20705.

Sample collection by Joe Hampton of the ENID Board of Trade and Rollie Sears of Kansas State University, and the assistance of Joyce Shaffer, ARS, in sample analysis are greatly appreciated.

An advantage of developing such a system is that NIR wheat hardness can be measured by most NIR instruments currently available for use with agricultural commodities. NIR instruments are used, for example, to measure protein in the national wheat inspection system, and to measure chemical components of forages and feedstuffs.

This publication presents the results of a study to determine the NIR hardness scores for a broad spectrum of wheat varieties grown at different locations. The scores represent an important first step in the development of a new wheat classification system. They form an initial data base from which some understanding may be gained about the effects of variety, growing conditions, and environment on wheat hardness. In addition, the values represent the first objective evaluation of wheat hardness nationwide and can help wheat growers, breeders, millers, and bakers select the wheat hardnesses best suited to their specific applications.

#### Procedure

Approximately 1,900 wheat samples were collected for this hardness study during the 1988 crop year. Samples were obtained from 10 States and include more than 125 varieties. Two sets of wheat samples were collected: one, drawn from commercial channels and identified as to variety by the farmer at the time of delivery to the local grain elevator; the second, from wheat breeders' variety trials. All samples were cleaned prior to analysis by official FGIS procedures to remove dockage and shrunken and broken kernels.

The samples (about 15 g per sample) were ground in a UDY cyclone grinder (model 3010-018), passed through a 1-mm screen, and analyzed with a Pacific Scientific spectrophotometer (model 6250).

Standardization of the NIR hardness measurement for the grinder, the spectrophotometer, and the laboratory technician involved in this study were conducted according to the AACC method by using the FGIS standard reference samples. The standardization for this study resulted in an average variance of 3 between replications.

#### Discussion

NIR hardness was developed on a scale of 0-100, 100 being the hardest. Soft wheats typically scored about 25 and hard wheats about 75. A specified hardness score does not necessarily imply the same level of quality to all end users, since the significance of a hardness value or range is established by the end user for each end product.

The NIR wheat hardness values are shown for the samples in tables 1-4. Tables 1 and 3 show the hardness values for the samples collected through commercial channels, while tables 2 and 4 show the hardness values for samples collected from the breeders' variety trials. Tables 1 and 2 are organized alphabetically by State abbreviation and then by region (city or county) within the State, and finally by NIR hardness within each variety. Tables 3 and 4 are organized alphabetically by variety and then by NIR wheat hardness within each variety. Table 5 summarizes the NIR hardness information by giving the average hardness value for each variety within each State.

In addition to information about wheat hardness for specified varieties and locations, the hardness tables provide information about the combined effects of variety and location on wheat hardness. For example, the four common hard red spring wheat varieties Butte-86, Len, Marshall, and Stoa show a general pattern of increasing hardness with increasing latitude. The soft

wheat variety Caldwell appears to be softer when grown in Kansas than when grown in Ohio or Missouri. Among the varieties of hard red winter wheat from Oklahoma or Texas, Mustang and Tam-101 could be expected to be harder than Chisholm.

Occasionally, the tables show that only a few samples were analyzed for a given variety and region. In those instances, the reader is reminded that the NIR hardness scores may not be representative of that variety over the entire region. Also, hardness values can fluctuate under varying environmental conditions, and the data presented here represent only wheat samples collected in the 1988 crop year. For example, the hardness values of wheats grown in Reno County, KS, are lower than expected because of kernel

shriveled due to a heavy infection by wheat streak mosaic virus. The variety names identified for the samples collected in this study were not verified, and the names shown may be incomplete in some cases.
